

## ABSTRACT

Author of research project	Žygimantas Benetis
Title of research project	Lithuanian Parliament Legislative Voting Analysis and Visualization
Supervisor	prof. dr. Tomas Krilavičius
Presented at	Vytautas Magnus university, Faculty of Informatics, Kaunas, 2019
Number of pages	46
Number of tables	15
Number of figures	12
Number of appendices	4
Lines of code	6605

In Republic of Lithuania, public elects their representatives to a parliament in which new legislation is considered. Due to nature of politics, a problem arises once citizens want to observe and evaluate parliament members work. Main output of parliament is their votes for various legislation. Voting data is publicly available through Parliament of the Republic of Lithuania (LRS) website. This project aims to visualize voting patterns and their changes. Another goal is to provide public access to results.

In the project Multidimensional scaling (MDS) [8] and *k-means* clustering are used to analyze voting patterns. Software to download, process and visualize data is written with Scala.

Atstovus į Lietuvos Respublikos Seimą (LRS), kuriame yra apsvarstomi ir priimami nauji įstatymai, išrenka Lietuvos piliečiai. Tačiau iškyla problemų visuomenei norint iš arčiau stebėti ir įvertinti Seimo narių darbą. Viena pagrindinių Seimo narių pareigų ir yra balsavimas priimant įvairius naujus įstatymus ar jų pataisymus. Kiekvieno Seimo nario balsai yra viešai prieinami Lietuvos Respublikos Seimo internetinėje svetainėje. Šiuo darbu siekiama šią informaciją vizualizuoti, kad būtų galima stebėti balsavimo modelius ir jų pasikeitimus. Taip pat yra siekiama suteikti viešą prieigą prie šių rezultatų.

Darbe, analizuojant balsavimo modelius, yra naudojamas daugiadimencinis skalių metodas ir k-reikšmių klasterizacija. Programinė įranga, duomenų atsisiuntimas ir vizualizavimas yra parašytas naudojantis Scala.

## GLOSSARY

***k-means*** *k-means* is a method of vector quantization, that is popular for unsupervised learning. It groups documents into subsets or clusters [1] . i, 1, 9, 10, 12, 19, 25–31

**atviras-seimas.lt** Domain and name of the project which is being created with the help of research done in this project . 11, 12, 14, 15

**dissimilarity matrix** It is a matrix which expresses the similarity of pair to pair between two sets [2]. 2

**draw.io** Online application for drawing diagrams and prototyping user interfaces. . 13

**Euclidian distance** It is a straight line in Euclidian space which marks distance between two points. . 19

**HTTP** Application protocol for distributed hypermedia systems . 18

**JVM** Abstract computing machine which acts like a virtual machine for programs running on it. [3] . 18

**LRS open data** Open data of Lietuvos Respublikos Seimas. 11, 19

**Mockup** Model of a design which is being built.. 13

**MySQL** is an open-source relational database management system . 3, 18

**Scala** Scala is a general-purpose programming language providing support for functional programming and a strong static type system . i, 18

# 1 INTRODUCTION

In Republic of Lithuania, public elects their representatives to a parliament in which new legislation is considered. By this election each citizen delegates specifics of legislation process to their representatives so they don't have to actively participate in the process.

However, a problem arises once citizen wants to validate what his representative has been doing. Single term of office involves thousands of complicated laws. This statistic can be observed in table 10, as there were 3933006 votes cast in total during 8 terms of office. To analyze everything becomes almost an impossible task for a single citizen who is out of the loop.

To make it easier there are journalists, politologists and other personas who review new legislation, current issues. Delegates themselves also do press conferences, debates where they state their intentions, comment on their actions. However, this requires citizens to trust that journalists and delegates only state truth, don't omit important information and don't have other hidden agendas. Study done about intrinsic honesty showed that the more society is corrupt - the more people lie in a simple dice game. This applies to politicians too and citizens trust in parliament is relatively low. Therefore, anything that can be done to better observe representatives is useful.

This project aims to deliver a software system which can be accessed online with research done available to any user. Research will include visualizations of Multidimensional scaling (MDS) for specific time periods of a given term. *K-means* projected on MDS output to visualize minority vs majority and to see if there are secret groups.

Research together with results were presented at "Lietuvos magistrantų informatikos ir IT tyrimai" conference. Scanned certificate can be found in Appendix 4.

## 2 ANALYSIS

### 2.1 Literature analysis

There is a decent amount of previous work analyzing voting on roll call data. A huge part of this research is on specific elections that happened in the past.

In *Spatial Models of Parliamentary Voting* [4] author discusses how voter's positions on specific issues can be captured by his position on one or two dimensions such as liberalism or conservatism. This constraint means there are two spaces - one with few dimensions - basic or ideological. The other - high dimensional space which represents remaining issues. This breakthrough might suggest Multidimensional scaling as a good performance method for visualization and analysis as majority of data is encoded in few dimensions.

There is research done specifically on LRS data. One such is *On Structural Analysis of Parliamentary Voting Data* [5]. In this paper authors discuss about data reduction to dissimilarity matrix, vote encoding, MDS and its performance on specific dimensions. Authors focus on specific elections and term of office which is different from our goal. However, methods discussed and research results are relevant for this project.

Master thesis was written few years ago on LRS voting which included similar analysis. One of research areas was to see if there are hidden groups in the parliament [6]. Author was not able to detect hidden groups. In this project, goal, data and parameters are different so conclusion might differ too. Method used was *k-means* clustering and data was showed on MDS reduced coordinates. In this project similar approach can be taken with different parameters like date ranges for votes.

In *The new Voteview.com: preserving and continuing Keith Poole's infrastructure for scholars, students and observers of Congress* [7] paper, authors discuss famous *Voteview.com* website. While website's primary goal is to provide open data access is different from ours - it contains useful information about how specific methods are used, how visualizations work. It also contains visualization which shows how data changed over time - how ideology and party composition changes.

## 2.2 Materials and methods

### 2.2.1 Lithuania's parliament open data semantics analysis

In this section open data from XML is reviewed. Only data and properties important to the project are included and commented on. All data is imported into MySQL database, therefore to demonstrate structure tables are used. Field types are inferred empirically by looking at data, therefore might not be correct in some cases. Moreover, data itself is not consistent through all years of Parliament of the Republic of Lithuania activity.

Table 1 contains term of office table structure.

Table 1. Term of office table structure

In XML	In database	Type	Comments
kadencijos_id	term_of_office_id	int(11)	Unique term of office id
pavadinimas	name	varchar(255) not null	Name
data_nuo	date_from	date not null	Date when term of office begins
data_iki	date_to	default null	Date when term of office ends

-	plenary_id	int(11) not null	Plenary id

## 2.3 Method analysis

### 2.3.1 MDS

Multidimensional scaling (MDS) is a method to visualize similarity of individual cases for a specific dataset. It takes an input matrix called proximity matrix  $\Upsilon$  (or distance matrix). Proximity matrix is symmetric matrix containing distances between all objects  $\psi$ . Or in more generic terms - it contains similarities or dissimilarities of pairs. Actual distance can be calculated using Euclidian distance as described in formula 1. Classic MDS will assume distance to be Euclidian.

$$d(\mathbf{p}, \mathbf{q}) = \sqrt{\sum_{i=1}^n (q_i - p_i)^2} \quad (1)$$

Method outputs coordinate matrix minimizes loss function *strain* [8]. Given proximity matrix  $\Upsilon$ , goal of MDS is to find  $\psi$  vectors  $q_1, \dots, q_\psi$  such that  $\|q_i - q_j\| \approx v_{ij} \forall i, j \in 1, \dots, \psi$ , where  $\|x\|$  is vector norm.

### 2.3.2 Unsupervised learning: *k*-means clusterization

*k-means* performance can be measured two ways: manually and with *distortion*. It is possible to inspect clusters and see if results given are somewhat correct. *Distortion* is final sum of the squared distances between each vector and its centroid [9].

## 2.4 Problem analysis

Problem can be divided into two pieces:

- Research part, including MDS and *k-means* classification
- Software development

If considered what is output of parliaments during their term of office in parliament - it would be their voting outcomes. Let's say there is a set of all votes made by parliament members  $V = \{v_1, v_2, \dots, v_n\}$  where each vote  $v_i$  has a tuple of parameters  $P = \{timestamp, term\ of\ office, parliament\ member\ id, voting\ outcome, \dots\}$ . Votes can be divided into groups depended on term of office  $T$  during which they were cast. Each term of office  $T_i$  can be divided into smaller arbitrarily chosen time periods  $\{p_1, p_2, \dots, p_n\}$ . Each time periods can have votes assigned which were cast during that time. Goal is to visualize set  $V$  in a way that similar voting patterns of different members are visible.

In order to visualize voting patterns by members, its dimensions need to be reduced. With help of Multidimensional scaling (MDS), vote set  $V$  with parameters set  $P$  can be visualized on a two or one dimensional coordinate system. As discussed in literature analysis and [4] voting patterns can be captured by only few dimensions. To observe how voting patterns change during time, different time periods could be chosen. Term of office should be the maximum time period  $p_n$  to analyze, as majority and minority usually changes together with parliament members.

Another goal is to see if votes can be classified to certain political groups' without knowing who voted. This also enables us to see if there are hidden factions between the explicitly stated ones. As discussed in literature analysis, in order to predict if voting pattern reveals political faction, majority or minority side, different amount of clusters need to be chosen. Finding clusters  $\{c_1, c_2, \dots, c_n\}$  representing political faction voting patterns and then assigning votes to the specifics clusters will show how similarly explicitly stated sides vote.

### 3 DESIGN AND DEVELOPMENT OF ATVIRAS-SEIMAS.LT

#### 3.1 Components of system

##### 3.1.1 Functional requirements

Main goal of software is to provide public access for masses to view analysis and research done in this project. Software will run on virtual server and be available online on atviras-seimas.lt. There are two main roles: guest user and scientist. Users will be able to access system with any modern browser. Scientist, or the person maintaining project will be able to update data to most recent one on LRS open data website.

Data is visualized using interactive diagrams. In table 9 functional requirements are presented.

Table 9. Functional requirements for atviras-seimas.lt

Requirement	User	Scientist
Access online with browser	✓	✓
View MDS results	✓	✓
Filter MDS results	✓	✓
Select different time periods for MDS results	✓	✓
View clustering results	✓	✓
Filter clustering results	✓	✓
Automatically download data with http query		✓
Automatically compute data with http query		✓

##### 3.1.2 Non-functional requirements

Non functional requirements:

- Page should load faster than 2 seconds
- Data should update in less than a day after query running
- User experience for users should be good
- System source code should be open source

##### 3.1.3 Data flow diagram

On atviras-seimas.lt software system data flow is visualized in figure 1. Scientist can initiate coordinator to start *Downloader* which will download data and clean data depending on the scientist query. Scientist can also initiate query which will process data with MDS or *k-means*.

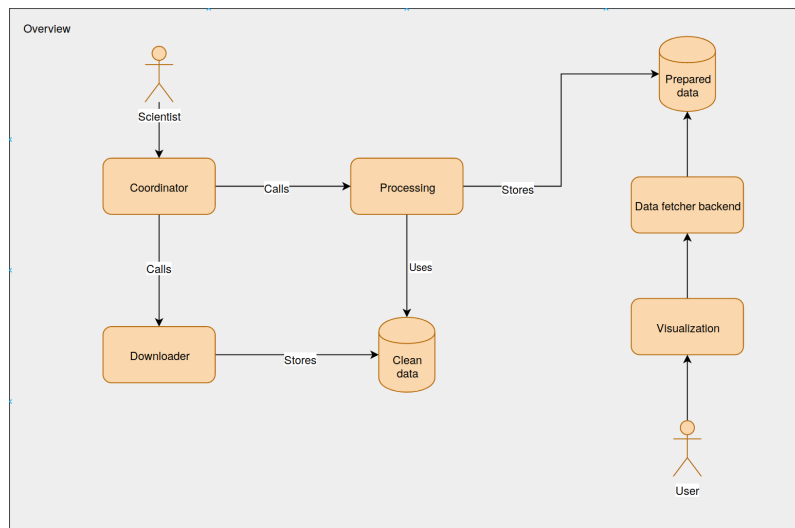

Figure 1. Data flow from database to *k-means*

## **3.2 User interface**

### **3.2.1 User flow**

Mockups are created for desktop size application with draw.io diagramming tool. These mockups show main user interaction flow for the application.

Mockups can be viewed in figures 2 and 3. In figure 2 it is visible that when user clicks landing page button, user is redirected to second screen with two tabs. Tab content can be visible together with filter controls. Clicking on tabs results into switching to another tab and can be seen on figure 3.

Tab content in figure 2 will include 2D graph showing Multidimensional scaling (MDS) results together with graph filter controls and faction list colors. Faction list will act as an legend for colors on the graph. Tab content in figure 3 will show results projected on previously calculated MDS coordinates.

Figure 2. Mockup of atviras-seimas.lt first screen

Figure 3. Mockup of atviras-seimas.lt second screen

### **3.2.2 Scala.js and React**

Scala.js is used to develop frontend part of software. As mentioned before, this enables types and common functions sharing between server and client part. Since Scala.js compiles to Javascript, all DOM API is available to use within Scala. For better library support and declarative style of development React framework is used.

### **3.2.3 Scatter plot**

To visualize voting patterns data needs to be projected on two or one dimensional plot. Each dot represented can be different parliament member and its position can indicate its voting pattern. The more scattered two points are - the more different voting patterns are. Each point can have color of faction to easier indicate clusters with human eye. Another important feature is view different time periods, even arbitrarily chosen. This enables users to inspect differences during term of office. Also it is worth to mention that parliament member change factions throughout term of office. For the sake of simplicity point color can be left to be faction color when member was elected to office. This approach has a drawback when looking at data changes during different periods, but it can keep things simplified.

### **3.2.4 Data filter**

For users to inspect data with more than hundred points, filtering for members and factions needs to be present. Users are able to filter data by word. It is possible to filter by one word or phrase, however multiple words or phrases can also be used. In addition, while filtering data users can choose different periods of time. All this helps to compare separate factions to one another or parliament members to factions.

(a) Data filter 1

(b) Data filter 2

Figure 4. Data filters

### **3.3 Tools**

#### **3.3.1 Programming language: Scala**

Both research and software parts of the project were done using Scala [10]. Scala choice is due its powerful type system and JVM libraries accessibility [11].

#### **3.3.2 Database: MySQL**

Since amount of data is relatively small as seen in experiment part - there is no need to consider data distribution problems. In this case the most important factor is to have fewer bugs. To achieve that Structured Query Language (SQL) is picked which has types for each column - MySQL [12].

### **3.4 API server**

This subsystem handles incoming HTTP requests from users. It uses *Akka-http* library [13]. Both computing and application requests are handled in this subsystem. Computing requests tell server to download specific set of data, update to newest data or order server to compute data for scientific methods. Application requests serve data to the client, querying it from the database. Since both client and server side are written with one programming language there are many benefits to use. While client side can remain as a single page application, server side can still share code with it. One such benefit - no need to write serializers and deserializers, since data types can be shared between two projects and process can be automatic.

### **3.5 Downloader**

Downloader's main aim is to download, clean and save data to database. Data flow can be viewed in figure 1. Downloader also has a feature to update just the data it is missing. It can be achieved two ways in this project: by requesting downloads for specifics terms of office or data ranges. Another way is just to download all of the data again, since all data has unique primary keys, data will not be duplicated and only new data will be added, leaving old data unchanged. Downloader does small pauses after each hit to LRS open data API. This is to prevent too much traffic at one time for the serving API. All of the data can be downloaded in few hours with this limitation.

### **3.6 Deployment**

Both server and client parts of the software are deployed to virtual machine on a datacenter. Client part artifacts are wrapped in Docker container and deployed to the virtual machine. Docker container is built locally by running a specific script. Server side is assembled into one archive file and moved to server where specific configuration with database password is passed through arguments. Database is installed locally on the virtual machine and is update migrated by hand.

### **3.7 Testing**

Software system code was tested using two techniques: white box and black box testing. For white box testing static analysis was done by the compiler. As mentioned before, Scala enables developer to constrain code with powerful types which are validated during compilation. This results in extremely powerful tool where a lot logic branches are written in algebras and their rules. Database schema has types set too, this prevents from problems like corrupted data when using wrong types. Black box testing was also performed. It involved manual clicking and testing against main flows of application and other functional and non-functional requirements.

## 4 DESCRIPTION OF EXPERIMENTAL RESEARCH

### 4.1 Data statistics

Data statistics are calculated from data LRS open data API which was downloaded and saved to local database. Quite a big chunk data from 1990-2012 is missing due to different information systems used at that time and other reasons. It was not migrated to current open data API. For this reason this project focuses more on recent data, but it is not limited to analyze older data too if it becomes available.

Table 10. Statistics of downloaded data

Name	Count
Terms of office	8
Sessions	101
Parliament members	1207
Plenaries	3977
Vote rows	3933006
Votes	28121
Agenda questions	64243
Plenary questions (2012-)	15108
Discussion events (2007-)	361996

### 4.2 Encoding of data

To use scientific methods, data needs to be prepared for them. Two methods: *MDS* and *k-means* need distances between pairs or training rows to compare parliament members to each other. This means that to compare one member's to another some measure like Euclidian distance is needed to produce numerical difference between points. Vote outcomes in given data are categorical, meaning they need to be converted to numbers. Since authors in [6] tried few vote encoding for MDS and LRS older data - this project will use different ones to capture broader scientific results. Data for experiments only includes current term, which start in 2016.

In table 11 chosen voting outcomes encoding can be viewed. *Encoding 1* straightforward scores are chosen. Voting abstain has negative score, because some legislature requires absolute majority to pass, therefore minority of parliament can block by abstaining. Did not vote is considered to be neutral, as some parliament members begin their term of office later and need to be assigned a score. *Encoding 2* values are chosen more flexibly. Voting for and against are opposites, however voting abstain and not attending are neutral. This is to cover the case where members actually vote not to block specific vote, but don't have opinion on how to vote. *Encoding 3* differs by having negative score for not voting at all. This is to cover the case where half or parliament members plus one is needed to pass certain laws, like changing constitution. This means that by not registering to vote you can actually vote against [14].

Table 11. Encoding of vote outcomes

Vote outcome	Encoding 1	Encoding 2	Encoding 3
For	2	1	2
Against	-2	-1	-2
Abstain	-1	0	-1
Did not vote	0	0	-1

Since factions are important part when viewing visualizations, they need to be consistent throughout graphs. Faction assigned colors can be viewed in figure

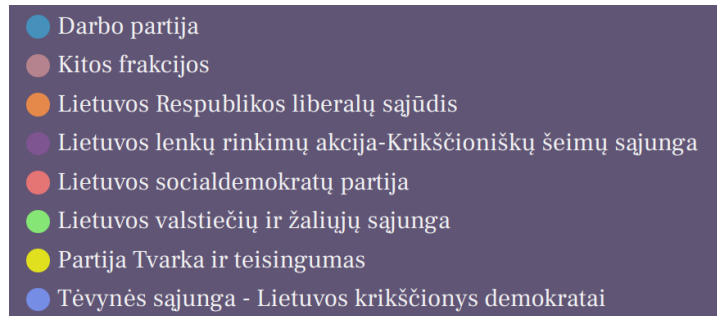

Figure 5. Colors assigned to factions in following visualizations

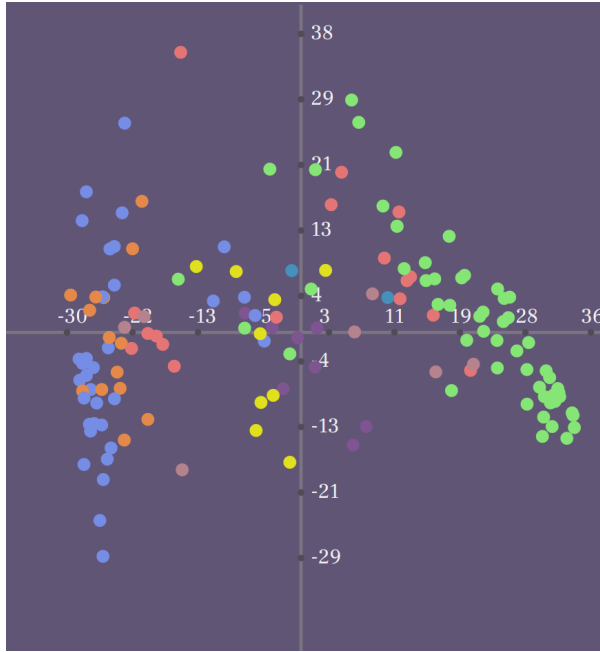

### 4.3 Multidimensional Scaling

To use MDS method proximity matrix needs to be generated. Distances need to be calculated from given data. Goal is to view voting patterns for given parliament members meaning that connection between somehow encoded votes and parliament members needs to be represented with this matrix.

In figures 6a, 6b, 6c MDS for current term of office is calculated and projected on 2d scatter plot. Three variants show how different vote encoding changes plot. Table 12 shows that *E2 encoding* has the highest proportion of variance of the scaled data which was accounted by MDS method. It shows that *E2 encoding* loses the least amount of data, meaning simple vote for and vote against is the best encoding for this case. Also, in visualization, faction voting patterns are clearly visible, as member votes are close to each other. Forming clusters.

Table 12. Proportion of variance for MDS

Encoding	Proportion of variance
E1	0.752
E2	0.790
E3	0.764

(a) encoding = E1

(b) encoding = E2

(c) encoding = E3

Figure 6. MDS on 2d scatter plot

#### **4.3.1 Time periods**

To get more insights, as discussed in problem analysis, data is split into 91.25 day periods. This enables to see what difference each of these periods introduce to the members. For example: Justas Džiugelis was a member of Greens majority faction during 2016-11-14 – 2018-09-10 period. If MDS were plotted to show how his voting is similar to his faction during current term of office - its possible to see how farther he gets before leaving the party. Comparison can be seen in figure 7, where green dots are members from his former faction, and light blue point is him. Before he leave the party on 2018-09-10, his voting patterns start to diverge starting 2018-02-01 voting period.

(a) 2016-11-01 — 2017-02-01

(b) 2017-02-01 — 2017-05-01

(c) 2017-05-01 — 2017-08-01

(d) 2017-08-01 — 2017-11-01

(e) 2017-11-01 — 2018-02-01

(f) 2018-02-01 — 2018-05-01

(g) 2018-05-01 — 2018-08-01

(h) 2018-08-01 — 2018-11-01

(i) 2018-11-01 — 2019-02-01

Figure 7. Changes in Justas Džiugelis voting patterns

## 4.4 Unsupervised learning: *k*-means clusterization

There are two goals for *k-means*: classify majority from minority and see if there are groups not explicitly split into factions.

Since some members joined parliament after term of office start or left it before it ended - data is missing on their votes during that time. To avoid this issue - empty training rows are added for that missing time.

Results from *k-means* are displayed on MDS calculated coordinates for the same time period. Training rows for clustering are prepared by encoding votes for given parliament member. Iteration count is 20.

### 4.4.1 Majority vs minority

Majority and minority are two groups which usually have different ideologies - they couldn't group up, therefore are voting differently on issues. Another experiment could be to test three groups - two for minority and majority and one for outsiders, parliament members who left one group or another, changed parties or are voting individually.

Figures 8a, 8b, 8c can be observed for results projected on MDS coordinates with fixed encoding *E1* for the same time period. Graphs show how parliament members are assigned to two clusters. Just from visual part it is not clear which encoding has best performance. From *K-means distortion* in table 13 shows *E2 encoding* to have the lowest value. Closer look at 8b suggests that most of points are classified correctly in this graph, white points being a minority and blue ones belonging to majority. This finding can also suggest that simple vote for and vote against split for positive negative score is the best as it was for MDS proportion of variance.

Table 13. Distortion for *k-means* majority vs minority results

Encoding	k=2	k=3
E1	536738	500433
E2	121566	116326
E3	854237	811270

(a)  $k=2$ , encoding = E1

(b)  $k=2$ , encoding = E2

(c)  $k=2$ , encoding = E3

Figure 8. majority vs minority,  $k$ -means on MDS coordinates

(a)  $k=3$ , encoding = E1

(b)  $k=3$ , encoding = E2

(c)  $k=3$ , encoding = E3

(d) Actual factions

Figure 9. majority vs minority,  $k=3$ ,  $k$ -means on MDS coordinates

Looking at figures 9a, 9b, 9c suggests that  $k=3$  is one cluster too much for  $E2$ ,  $E3$  encodings as it doesn't show anything meaningful. 9a figure shows points which are more truthful, white points being people who are outsiders as predicted in hypothesis.

#### 4.4.2 Secret groups

There are 8 factions in current term of office. 8th faction is mixed group, meaning they will not vote in unison. In perfect scenario remaining 7 factions should be classified by classifier. To see how differently voting patterns can group - one group with less than 7 clusters should be tried and another one with more than 8 to see how well it matches current factions.

Table 14. Distortion for *k-means* secret groups results

Encoding	k=7	k=8	k=9
E1	446888	432739	428739
E2	100255	99660	98591
E3	706380	694879	688514

Name	Surname	Part of factions in office
Juozas	Bernatonis	2
Irena	Šiaulienė	2
Algimantas	Salamakinas	2
Gediminas	Kirkilas	2
Linas Antanas	Linkevičius	2
Antanas	Vinkus	2
Juozas	Olekas	2
Algirdas	Butkevičius	2
Petras	Gražulis	2
Algirdas	Sysas	2
Rasa	Budbergytė	2
Raimundas	Martinėlis	2
Julius	Sabatauskas	2
Naglis	Puteikis	2
Rimantas	Sinkevičius	2
Gintaras	Steponavičius	2
Mindaugas	Bastys	3
Artūras	Skardžius	2
Valentinas	Bukauskas	4
Mantas	Adomėnas	2
Rimantė	Šalaševičiūtė	2
Linas	Balsys	2
Petras	Čimbaras	2
Andrius	Palionis	2
Raminta	Popovienė	2
Povilas	Urbšys	2
Bronislovas	Matelis	2
Mindaugas	Puidokas	2
Kęstutis	Pūkas	2
Dovilė	Šakalienė	3
Rimas	Andrikis	2
Aušrinė	Armonaitė	2
Justas	Džiugelis	2

Table 15. Members who changed their faction at least one time in current term of office

In figures 10a, 10b, 10c  $k = 7$  parameter setting is tested. All encoding versions show similar distribution to actual faction if we exclude the ones who changed a faction during the term. Members who did can be seen in table 15. These findings also show that for biggest minority and majority parties there are main clusters where members vote ideologically and there at least a third of members who vote more differently. This means that party members do not follow same

(a)  $k=7$ , encoding = E1

(b)  $k=7$ , encoding = E2

(c)  $k=7$ , encoding = E3

(d) Actual factions

Figure 10. different clusters of members, *k-means* on MDS coordinates

ideology, just a similar one. This finding suggests that some citizens might be betrayed.

(a)  $k=8$ , encoding = E1

(b)  $k=8$ , encoding = E2

(c)  $k=8$ , encoding = E3

(d) Actual factions

Figure 11. different clusters of members,  $k$ -means on MDS coordinates

In figures 11a, 11b, 11c  $k = 8$  parameter setting is tested. Graphs seem to suggest that minority is working together on some issues, but still vote differently on others. Difference from  $k = 7$  can be seen with more outliers in the center.

(a)  $k=9$ , encoding = E1

(b)  $k=9$ , encoding = E2

(c)  $k=9$ , encoding = E3

(d) Actual factions

Figure 12. different clusters of members, *k-means* on MDS coordinates

In figures 12a, 12b, 12c  $k = 9$  parameter setting is tested. *E3* encoding graph is accurate to split majority greens faction voting. It splits main cluster which votes together from outliers who take high position posts or left the faction. Same encoding splits some liberals from conservatives well, although voting patterns are similar on the plot.

## 4.5 Results

1. Literature analysis was done to find out similar research to this project's topic.
2. Data semantics and structure of open data API were reviewed.
3. Problem and method analysis were done to write in better detail about the problem and its goals.
4. Data statistics were counted to understand size of the data set.
5. Experiments were done with MDS and to tweak hyper parameters.
6. Visualizations were created according to research results.
7. Software to serve API requests and process the data according to research done was developed.
8. Custom components, scatter plot and data filter, were specifically developed to visualize data.
9. User interface was designed and developed.
10. Software was deployed to data center's virtual server and made available to public.

## 4.6 Conclusions

1. Confirmed that Multidimensional scaling (MDS) works well to visualize voting patterns. Reason is probably due ideology behind parliament member choices as stated by [4].
2. Splitting voting data into fixed periods and analyzing them against each other can give insight if certain members will change political faction due their voting patterns becoming different from their faction.
3. Using *k-means* on voting patterns data can roughly classify majority from minority giving insights on possible future alliances.
4. *k-means* can discern interesting results how politicians are grouped by their votes, especially highlighting few different voters from the majority of specific faction.
5. *k-means* can be quite accurate to help visualize specific voting patterns with specific amount of clusters. Secret factions cannot be seen by simple glimpse, but by deeper analysis some smaller groups in factions can be found. Especially splitting members who take other positions from their faction voting pattern.
6. Scala ability to compile to both JVM and Javascript proved useful. This is due RPC being done with help of macros. It enabled shared data types between server and client.

## **A APPENDIX**

### **A.1 Research project no. 1 summary**

Author of research project	Žygimantas Benetis
Title of research project	Detecting and analysing computer generated comments
Supervisor	prof. dr. Tomas Krilavičius
Presented at	Vytautas Magnus university, Faculty of Informatics, Kaunas, 2017
Number of pages	14
Number of tables	9
Number of figures	5
Number of appendices	1

In this research project problem of internet bots was considered. Specifically ones which post to forums, comments sections on twitter. Since economic incentive behind bots is big, they were getting more and more popular. In the project most popular Lithuanian news website delfi.lt dataset of all comments written after articles was analyzed. Literature was reviewed to see similar work done on this topic. Data was inspected to see the properties, problem analysis and project plan done to plan future work on this topic.

## A.2 Research project no. 2 summary

Author of research project	Žygimantas Benetis
Title of research project	Detecting and analysing comments
Supervisor	prof. dr. Tomas Krilavičius
Presented at	Vytautas Magnus university, Faculty of Informatics, Kaunas, 2018
Number of pages	15
Number of tables	1
Number of figures	15
Number of appendices	0

In this research project work on same problem was continued. To classify comments on internet website delfi.lt. More statistics and visual graphs needed to be done to find patterns and better choose methods for experiment part. Since amount of data did not fit into computer memory, more complex algorithmic solutions were required to deal with this problem. *Term Frequency Inverse Document Frequency* and *k-means clusterization* were chosen to work with. Pipelines for experimental research were designed and developed to reproduce research and compute in a faster manner.

### A.3 Research project no. 3 summary

Author of research project	Žygimantas Benetis
Title of research project	Analysis and classification of online comments intentions
Supervisor	prof. dr. Tomas Krilavičius
Presented at	Vytautas Magnus university, Faculty of Informatics, Kaunas, 2018
Number of pages	8
Number of tables	1
Number of figures	2
Number of appendices	1
Lines of code	2010

In this research project work on same problem was continued. More detailed method analysis, more detailed performance evaluation and use of statistics were employed to help achieve results. Architecture for data pipelines was finalized and used to produce the results. Data extraction and other pipelines could be reused and research can be reproduced even for huge amounts of data. This is due to the use of distributed big data library Spark. Final thesis project plan was added, however, due to lack of results produced by the methods decision was made not to follow up and choose a different topic.

## A.4 Conference certificate

# Pažymėjimas

**Žygimantas Benetis**

Vytauto Didžiojo universitetas

dalyvavo Lietuvos mokslų akademijos  
mokslinėje konferencijoje

**Lietuvos magistrantų informatikos  
ir IT tyrimai**

ir skaitė pranešimą
